

Algorithm to Solve PDE Models

MATTHIEU GOMEZ *

March 15, 2017

This note details an algorithm with excellent convergence properties to solve PDEs associated with economic models in continuous time.

1 Solving Finite Difference Schemes

1.1 How Ψtc works

Denote Y the solution and denote $F(Y) = 0$ the finite difference scheme corresponding to a model. One can solve for Y using one of the two methods:

1. Non linear solver for $F(Y) = 0$. Updates take the form

$$0 = F(y_t) + J_F(y_t)(y_{t+1} - y_t)$$

The method converges only if the initial guess is sufficiently close to the solution.¹

2. ODE solver for $F(Y) = \dot{Y}$. The solution of $F(Y) = 0$ is obtained with $T \rightarrow +\infty$.² With a simple explicit Euler method, updates take the form

$$0 = F(y_t) - \frac{1}{\Delta}(y_{t+1} - y_t)$$

Convergence conditions are given by the Barles-Souganadis theorem. Explicit schemes usually don't satisfy them.

I propose to use a fully implicit Euler method, which has better convergence properties than explicit schemes. Updates take the form

$$\forall t \leq T \quad 0 = F(y_{t+1}) - \frac{1}{\Delta}(y_{t+1} - y_t)$$

Each time step is a non linear equation, which I solve using a Newton-Raphson method. These inner iterations take the form

$$\forall i \leq I \quad 0 = F(y_t^i) - \frac{1}{\Delta}(y_t^i - y_t) + (J_F(y_t^i) - \frac{1}{\Delta})(y_t^{i+1} - y_t^i)$$

*I thank Valentin Haddad, Ben Moll, and Dejanir Silva for useful discussions.

¹For instance, see Campbell and Cochrane (1999).

²For instance, see Di Tella (2016).

As pointed above, the Newton-Raphson method converges when y_t is sufficiently close to y_{t+1} . Therefore I decrease Δ until the inner Newton-Raphson method converges.³.

I accomodate algebraic equations by setting $\Delta = +\infty$ for these equations. This ensures that the PDEs are solved backward on a path that always satisfies the algebraic constraints.

How does the method relate to the two algorithms seen above? When $I = 1$ (i.e. with only one inner iteration) the update can be seen as the sum of a Newton-Raphson and an explicit time step

$$\forall t \leq T \quad 0 = F(y_{t+1}) + (J_F(y_t) - \frac{1}{\Delta})(y_{t+1} - y_t)$$

Alternatively, the method can be also be seen as a dampened Newton-Raphson algorithm. As in the Levenberg-Marquardt method, the diagonal of the Jacobian is modified until the algorithm gets close to the solution.

The algorithm usally converges quickly: the convergence is quadratic around the solution, since the algorithm follows the Newton-Raphson method around the solution.

1.2 Related Methods

- With $I = 1$ and constant Δ , we obtain the method in Achdou et al. (2016) for a partial equilibrium consumption / saving problem with separable preference. I've found that allowing Δ to change and a $I > 1$ are important for the robustness of the algorithm. Moreover, Ψtc handles systems with implicit jacobians and algebraic equations.
- A similar algorithm is used in Fluid Dynamics. In this context, it is called Pseudo-Transient Continuation (denoted Ψtc).

2 Writing Finite Difference Schemes

- Write the finite difference scheme so that the implicit Euler method satisfies the convergence conditions of Barles-Souganadis theorem (as much as possible). In particular,
 - Upwind first derivatives to make the scheme monotonous (for instance see Achdou, Han, Lasry, Lions (2016))
 - Write the function F so that \dot{Y} would appear as such (i.e. not multiplied by some parameters). For instance, a typical PDE for the price

³However, I cannot prove the convergence of the overall scheme when Δ depends on the step. The Barles-Souganadis theorem ensures that the implicit Euler scheme converges only with Δ fixed. Kelley and Keyes (1998) provides the formal proof of convergence for the algorithm with some supplementary assumptions on F

dividend ratio should be written

$$0 = p\left(\frac{1}{p} + E\left[\frac{dD}{D}\right] + E\left[\frac{dp}{p}\right] + \sigma\left[\frac{dp}{p}\right]\sigma\left[\frac{dD}{D}\right] - r - \kappa(\sigma\left[\frac{dp}{p}\right] + \sigma\left[\frac{dD}{D}\right])\right)$$

- When solving for multiple functions, use the same economic quantities across the different equations. This ensures that the time step is comparable across different equations. For instance use the wealth / consumption of each agent in heterogeneous agent models.
